----- SUPER COMPUTER OPERATIONS -----

1.0 SCOPE

This timing specification is intended for persons already having familiarity with CYBER 200 concepts, terminology and general description as contained in the applicable specifications. In particular, this timing specification depends on much of the material in the CYBER 205 Functional Computer Specification 10358025. The times contained in this specification for the CYBER 205 are preliminary estimates with little verification being complete at this time.

In general, those instructions executed will be verified via simulation.

2.0 APPLICABLE DOCUMENTS

(To be added)

3.0 REQUIREMENTS

3.1 General Description

The tables in Section 3.2 are designed to provide timing data for the instruction sequences in the CYBER 205. All timing data is expressed in 20 nsec. minor cycles.

----- SUPER COMPUTER OPERATIONS -----

3.1 (Continued)

Scalar instructions are expressed as described below.

The ISSUE column of the tables contains the minimum number of minor cycles between the issue of the specific instruction listed in the left column and the issue of the next instruction in the sequence. Various operand or memory conflicts (as discussed later) can cause additional delay beyond this minimum time.

The Issue column of the tables is sub-divided when appropriate into three categories as defined below:

- NB -- No Branch
- ISB -- In Stack Branch
- OSB -- Out of Stack Branch to first quarter sword. This time must be increased by 1, 2 or 3 if the Branch address is in the 2nd, 3rd or 4th quarter sword respectively.

The non-branch instructions use the entry under NB or No Branch. Example 1 illustrates a simple, no conflict, Branch sequence.

For this example and all following examples, the calculations are based on values from tables 3.1-1, 3.2-1 and 3.2-2. The times under each column are based on Issue or Busy (L/S or D/C) time plus SS, RF and MEM.

The R, S, T, A, X, Y, B, C, and Z under instruction represents the appropriate descriptors from the instruction. Non pertinent data is represented by a -.

SUPER COMPUTER OPERATIONS

Example 1

TIME												
INSTRUCTION												
	F	R/G	S/X	T/A	F.P.	RESULTS			BUSY		REGISTER	
	Y	B	Z	C	ISSUE	STACKED	SS	RE	MEM	L/S	D/C	RELEASE
A)	60	-	-	-	0	-	5	8	-	-	-	-
B)	25	-	-	-	1 (NB)	-	-	-	-	-	-	-
-----//-----												
					11							
C)	60	-	-	-	12	-	17	20	-	-	-	-
D)	25	-	-	-	13 (OSB)	-	-	-	-	-	-	-
-----//-----												
					41							
E)	-	-	-	-	42							

Instruction (B) is a branch with condition not met; therefore instruction (C) issues at time 12.

Instruction (D) is a branch with condition met to instruction (E) whose address is out of stack and falls in the third quarter sword therefore; (E)'s

$$\begin{aligned}
 \text{Issue} &= \text{Time } 13 + \text{OSB (D)} + \text{3rd Quarter Sword} \\
 &= 13 + 27 + 2 \\
 &= 42.
 \end{aligned}$$

The RESULT AVAILABLE column of the tables contains information necessary to time instruction sequences with operand dependencies. The first column, SS or shortstop, contains entries for those instructions which use the Floating Point Unit. These are the instructions which may use the shortstop feature to provide an input operand. This entry is the number of minor cycles after issue that the result operand will be available at the shortstop for use with a following instruction.

If instruction A issues at minor cycle X, any following instruction, B, needing the result of A must issue no later than minor cycle X+SS to utilize the shortstop. A floating point instruction needing the result of A, can be issued before X+SS and wait at the input of floating point for the shortstopped result of A. This allows other non-floating point instructions

----- SUPER COMPUTER OPERATIONS -----

(12,13,2F,31,32,35,36,5E,5F,7E,7F, (B0-B5)(.XX0X-X) and B6) to issue. The resulting time of an instruction that issues and waits for shortstop will be as if it had issued at the ideal time to match shortstop. A subsequent instruction requiring access to floating point will not issue any earlier than {X+SS} + 1.

If instruction B issues later than cycle X+SS, thus missing the shortstop; instruction B must wait until at least X+RF. At this time the desired operand will be available from the Register File. Example 2 illustrates operations using shortstop.

NOTE: Instructions that require 64-bit operands cannot shortstop the result of a 32-bit operation and vice versa.

Example 2

INSTRUCTION	TIME											
	F	R/G	S/X	T/A	F.P.	RESULTS			BUSY		REGISTER

					21	(M)						
					22	-	25	28	-	-	-	-

----- SUPER COMPUTER OPERATIONS -----

Instruction (F) has a source operand conflict with Instruction (A) whose SS time 5 matches instructions (F)'s earliest issue time 5, therefore no delay in issue.

Instruction (G) has a source operand conflict with Instruction (F) and has to wait until Instruction (F)'s SS time 10 before it can proceed but because one instruction can be stacked in front of the F.P. unit Instruction (H) can issue and execute.

Instruction (J) has a source operand conflict with Instruction (F). The earliest it can issue is time 12 and misses Instruction (F)'s SS time 10, therefore it has to wait until RF time 13 of instruction (F).

Instruction (K) has a source conflict with instructions (I) and (J). It tries to issue as early as time 14, but has to wait until time 18 which is the latest SS time of Instruction (I) and (J). It will stack in front of the F.P. unit but does no good in this case because the following instruction needs the same unit.

Instruction (M) has a register file write conflict and must wait until the next available RF opening before it can issue.

The last column under RESULT AVAILABLE (MEM) contains entries for those scalar instructions (13, 32, 5F, 7F) which store a result into Central Memory. The time listed is the minimum time until the operand is in memory and available for use. The time may also be increased by 4 minor cycles if the desired memory bank is busy.

The UNIT BUSY column of Table 3.2-1 concerns Instructions issued to either the Divide/Convert (D/C) Unit or the Load/Store Unit (L/S). The Divide/ Convert Unit executes the 10, 11, 4C, 4F, 53, 6C, 6F and 73 instructions.

This unit is the only portion of Floating Point which is not a Pipe; thus the appropriate unit busy time listed in Table 3.2-1 must elapse before another instruction can be issued to the Divide/Convert Unit. Floating Point instructions other than these eight may be issued to Floating Point while the Divide/Convert Unit is busy.

----- SUPER COMPUTER OPERATIONS -----

A second instruction from the set of eight can be issued, but will be held in front of the Floating Point Unit and issuing of non-floating point instructions will continue.

The Load/Store Unit executes the 12, 13, 32, 5E, 5F, 7E and 7F instructions. There are six address registers in the Load/Store Unit which enable requests to be stacked and executed in the proper order. The 12, 5E and 7E instructions each require one register and can be executed (in the absence of memory conflicts) at the rate of one load per minor cycle. The 5F and 7F instructions each require two address registers and can be executed at one store per two minor cycles. The 13 and 32 (not if G bits 2 & 3 = 0) instructions each require two address registers and can be executed at one per 14 and 15 minor cycles, respectively. The rate is determined from the unit busy (see table 3.2-1).

The LOAD/STORE Unit is then capable of streaming Load/Store instructions (other than the 13 and 32) at one minor cycle per load and two minor cycles per store assuming no Memory or Register File conflicts. For example, a stream of N loads will execute in  $N + 14$  minor cycles from the issue of the first load until the operand from the last load is available in the Register File. The  $N + 14$  comes from table 3.2-1 where the 14 is the RF time minus 1.

The method of determining the time of issue for a load/store instruction that is waiting on address registers to be released from previous load/store operation is as follows:

$$A + B + 5 \text{ M.C. (minor cycles)} \\ \text{(for register release)}$$

Where A is the unit busy time from Table 3.2-1 for the instructions that release the register.

Where B is the sum of unit busies stacked up prior to A.

The method for determining result calculations for an instruction that waits on a unit busy and is already issued, is to substitute the previous unit busy accumulated time and add the instructions SS, RF and/or busy time. See Example 3.

----- SUPER COMPUTER OPERATIONS -----

A sequence of loads and store do not reference memory out of order. Therefore, a store followed by a load to the same location results in a delayed load of one memory busy (4 M.C.) minimum.

Example 3

INSTRUCTION					TIME							
F	R/G	S/X	T/A		F.P.	RESULTS			BUSY		REGISTER	
<u>Y</u>	<u>B</u>	<u>Z</u>	<u>C</u>	ISSUE	STACKED	SS	RF	MEM	L/S	D/C	RELEASE

F)	60	-	-	-	5	-	-	-	39	30	-	
F)	60	-	-	-	6	-	11	14	-	-	-	
F)	7E	-	-	-	7	-	-	45	-	31	-	
G)	7E	-	-	-	8	-	-	46	-	32	-	
H)	7E	-	-	-	9	-	-	-	-	-	37	
-----//-----												
					21	-	-	47	-	33	-	
I)	13	-	-	-	22	-	-	-	-	-	38	
-----//-----												
					36	-	-	-	56	47	-	
J)	6F	-	-	-	37	-	91	94	-	-	87	
K)	6F	-	-	-	38	-	-	-	-	-	-	
L)	-	-	-	-	39	(K)	-	-	-	-	-	
-----//-----												
					87	(K)	141	144	-	-	137	

Instruction (B) is a load instruction and its calculations are:

$$\begin{aligned} \text{L/S Busy} &= \text{Issue} + \text{L/S} = 1 + 1 = 2 \\ \text{Register Release} &= \text{Busy} + 5 = 2 + 5 = 7 \\ \text{Result RF} &= \text{Issue} + \text{RF} = 1 + 15 = 16 \end{aligned}$$

Instruction (C) is a byte store and calculations are based on issue time 2 or prior L/S busy time 2, whichever is largest, in this case either can be used.

$$\begin{aligned} \text{L/S Busy} &= \text{L/S busy} + \text{L/S} = 2 + 14 = 16 \\ \text{Register Release} &= \text{L/S busy} + 5 = 16 + 5 = 21 \\ \text{Mem} &= \text{L/S busy} + \text{Min} = 2 + 23 = 25 \end{aligned}$$

----- SUPER COMPUTER OPERATIONS -----

Instruction (D) is a byte store and the busy time is greater than issue time therefore:

$$\begin{aligned} \text{L/S Busy} &= \text{L/S busy} + \text{L/S} = 16 + 14 = 30 \\ \text{Register Release} &= \text{L/S busy} + 5 = 30 + 5 = 35 \\ \text{Mem} &= \text{L/S busy} + \text{Mem} = 16 + 23 = 39 \end{aligned}$$

Load Instruction (F's) times will be based on busy.

$$\begin{aligned} \text{L/S Busy} &= \text{L/S busy} + \text{L/S} = 30 + 1 = 31 \\ \text{Register Release} &= \text{L/S busy} + 15 = 31 + 5 = 36 \\ \text{RF} &= \text{L/S busy} + \text{RF} = 30 + 15 = 45 \end{aligned}$$

Instruction (G) is the same as instruction (F) therefore all calculations will be 1 greater.

Instruction (H) is the same as Instruction (G) but its issue will be held up because the 6 registers in Load/Store are busy by Instruction (C) uses 2, (D) uses 2, (F) and (G) uses 1 apiece and will not issue until register release of instruction (C) time 21.

$$\begin{aligned} \text{L/S Busy} &= \text{L/S busy} + \text{L/S} = 32 + 1 = 33 \\ \text{Register Release} &= \text{L/S busy} + 5 = 33 + 5 = 38 \\ \text{RF} &= \text{L/S busy} + \text{RF} = 32 + 15 = 47 \end{aligned}$$

Instruction (I) cannot issue because 5 of 6 registers are busy and must wait until instruction (D) register release time 35, therefore:

$$\begin{aligned} \text{L/S busy} &= \text{L/S busy} + \text{L/S} = 33 + 14 = 47 \\ \text{Register Release} &= \text{L/S busy} + 5 = 47 + 5 = 52 \\ \text{Mem} &= \text{L/S busy} + \text{Mem} = 33 + 23 = 56 \end{aligned}$$

Instructions (J) and (K) use the D/C busy which is not busy therefore (J) issues at time 37 and its calculations are based on time 37.

$$\begin{aligned} \text{SS} &= \text{ISSUE} + \text{SS} = 37 + 54 = 91 \\ \text{RF} &= \text{ISSUE} + \text{RF} = 37 + 57 = 94 \\ \text{D/C Busy} &= \text{ISSUE} + \text{D/C} = 37 + 50 = 87 \end{aligned}$$

Instruction (K) calculations will be based on D/C busy which is greater than issue time.

$$\begin{aligned} \text{SS} &= \text{D/C busy} + \text{SS} = 87 + 54 = 141 \\ \text{RF} &= \text{D/C busy} + \text{RF} = 87 + 57 = 144 \\ \text{D/C busy} &= \text{D/C busy} + \text{D/C} = 87 + 50 = 137 \end{aligned}$$

Instruction (L) can issue at time 39 and execute if it is a non F.P. instruction, otherwise it must wait until time 88.

----- SUPER COMPUTER OPERATIONS -----

There are three Operand Dependencies which delay issue that must be considered.

1. Source operand conflict -- an instruction requiring the result of a previous instruction as an input operand waits until the operand becomes available.
2. Output operand conflict -- an instruction output to the same Register File location as a previously issued, but slower instruction, waits until the previous instruction stores its result in the Register File, unless it also has a source operand conflict then it will go at the shortstop time.
3. Register File Write conflict -- an instruction cannot issue if its result arrives at the Register File at the same minor cycle as the result of a previously issued but slower instruction.

Table 3.1-1 pertains to instructions having greater than 1 minor cycle issue time.

The first column lists the appropriate instructions. The second column indicates the minor cycle of issue that a specific operand is required. The third column indicates the availability of shortstop for that specific operand.

Example 4

					TIME							
INSTRUCTION												
	F	R/G	S/A	T/A	F.P.	Results			BUSY		REGISTER	
	<u>Y</u>	<u>B</u>	<u>Z</u>	<u>C</u>	<u>ISSUE</u>	<u>STACKED</u>	<u>SS</u>	<u>RF</u>	<u>MEM</u>	<u>L/S</u>	<u>D/C</u>	<u>RELEASE</u>

B)	31	12	-	-	1							
					7(OSB)							
C)	60	-	-	35	31	-	36	39	-	-	-	-
D)	20	35	35	-	32							
					33							
					34							
					35							
					36(ISB)							
E)	60	-	-	-	47							

----- SUPER COMPUTER OPERATIONS -----

Instruction (B) branches out of stack to instruction (C) (in second quarter sword). Its issue occurs at time 7, as opposed to time the RF time of instruction that it depended on. The R descriptor is in the second cycle (from table 3.1) therefore:

$$\begin{aligned} \text{Issue} &= \text{Issue} + \text{OSB} + 1 \text{ (second quarter sword)} \\ &= 7 + 23 + 1 = 31 \end{aligned}$$

Instruction (D) branches in stack to instruction (E) and is dependent on instruction (D)'s SS time 36. Because (D) R & S descriptors are read in the second cycle, issue starts at time 35. Calculations are:

$$\text{Issue} = \text{Issue} + \text{ISB} = 35 + 12 = 47$$

Timing descriptions for those instructions in the vector/string units are as follows.

Each instruction has two values in its timing equations. One value is issue time (INB) which is the amount of time the issue unit spends on this instruction. The other value is a busy time (VBA). Overlap does occur in most cases between vector/string instructions (table 3.2-2) and scalar instructions (table 3.2-1). The exceptions are those instructions in table (3.2-2) that do not have a (VBA) time.

The busy time (VBA) represents the number of cycles of parallel work that can be accomplished by the scalar instructions before the next vector/string unit instruction will be executed. Overlap does not occur if the scalar instruction requires the load/store unit instructions (04, 0C, 0D, 0F, 12, 13, 32, 5E, 5F, 7E and 7F). In this case, busy time (VBA) is used to predict the execution start time for these instructions the same way it is used to predict execution start time for a vector/string instruction. Their results and busy times will be increased from (15-23) minor cycles because of common hardware between table 3.2-2 instructions and load/store unit instructions. The start time of a vector string instruction is influenced by a preceding load/store unit instruction. The vector/string operation will start when the load/store unit busy has 10 minor cycles remaining.

Table 3.2-2 lists the instruction OP-CODE in the first column, then the issue time in minor cycle, the busy times in minor cycles and in the last four

----- SUPER COMPUTER OPERATIONS -----

3.1 (Continued)

columns are the rate factors or pipe line size (PLS). The PLS is given for both 2 and 4 pipe size CPU's. PLS is the number of elements per minor cycle and is constant or has different values for elements of 32 bit (32M) and 64 bit (64M) moves.

Example 5 - C=40 and PLS=2 for vectors

Instruction (E) will start issue at time 4 even though designator B's contents are not available until time 6 (instructions (C) RF time) because table 3.1-1 shows it is not needed until the fourth cycle of the instruction.

Instruction (F) will issue at time 21 using table 3.2-2.

----- SUPER COMPUTER OPERATIONS -----

3.1 (Continued)

$$\text{Issue} = \text{Issue} + \text{INB}(E) = 4 + 17 = 21$$

Instruction (P) will issue at time 93 because the VBA  
 (=34 + 140 of E), is greater than issue time spent by  
1 21

Instructions (F) through (N) therefore:

$$\begin{aligned} \text{Issue} &= \text{Issue (F)} + \text{VBA}(E) + \text{INB}(O) = 21 + 34 \\ &\quad \underline{140} \\ &\quad \underline{1 21} + 18 = 93 \end{aligned}$$

Instruction (U) will issue at time 314 because  
 instruction (U) is a load and cannot start until  
 instruction (O)'s busy is expended therefore:

$$\begin{aligned} \text{Issue} &= \text{Issue (P)} + \text{VBA}(O) = 93 + 62 + \underline{1 40} = 280 \\ &\quad \underline{1.321} \end{aligned}$$

Instruction (U)'s result to register file RF will be  
 delayed by an additional 15 minor cycles minimum  
 because of the previous vector instruction.

Timing of link operation

The total INB time for a link operation is the sum of  
 INB's for the 56 instruction F1 and F2. The VBA time  
 is the longer of F1 or F2.

All times are approximate due to small variations  
 listed under assumptions for vectors.

Assumptions

Calculation using tables does assume an ideal situation  
 and time must be added for the following:

1. Alignment of slot time for memory reference, up to 7  
 minor cycles.
2. Space table searches in job mode:  $34 + \frac{N}{2}$  where N is  
 number of element to search.
3. Interrupts.
4. Vector conflict with I/O 0-32 minor cycles only if  
 there is a control vector. Not a high probability.

3.1 (Continued)

5. Starting bank address of input streams and output stream could add 4, 8 or 12 cycles.
6. Register file conflicts are calculated the same as scalar instructions by using Table 3.1.1. The exact cycle the register is needed for the vector instruction can be obtained from the table.

Table 3.2-2

Definitions for Table 3.2-2

32M = 32 Mode Operation

64M = 64 Mode Operation

PLS = Pipe Line Size (Number of elements per minor cycle)

$\lceil \quad \rceil$  = The ceiling defined as the nearest integer greater than  
 or equal

\  
 A |  
 B |  
 C | These letters stand for usable length of their resoeective  
 X | fields, that is: B's field length of a field etc. Usable  
 Y > field length means given field or sometimes requires the  
 Z | subtraction of its offset.  
 R |  
 S |  
 T |  
 /

$$CR = \frac{\lceil C \rceil}{PLS}$$

$$ZR = \frac{\lceil Z \rceil}{PLS}$$

$$BR = \frac{\lceil B \rceil}{PLS}$$

$$AR = \frac{\lceil A \rceil}{PLS}$$

$$ABR = \frac{\lceil A \rceil}{PLS} \text{ OR } \frac{\lceil B \rceil}{PLS} \text{ Use smaller of the two}$$

$$TRA = \left( \frac{\lceil I \rceil}{PI} \right) \left( \frac{\lceil R \rceil}{16} + \frac{\lceil S \rceil}{16} \right)$$

SUPER COMPUTER OPERATIONS

Table 3.2-2

Definitions for Table 3.2-2 (Continued)

$$TRB = \left( \frac{\overline{I} \overline{I}}{IR+S} \right) + \left( \frac{\overline{I} \overline{P}}{16} + \frac{\overline{I} \overline{S}}{16} \right)$$

$$TRC = \left( \frac{\overline{I} \overline{I}}{S} \right) + \left( \frac{\overline{I} \overline{R}}{16} + \frac{\overline{I} \overline{S-R}}{16} \right)$$

$$TR = \left( \frac{\overline{I} \overline{I}}{2} \right) \text{ or } \left( \frac{\overline{I} \overline{R}}{2} \right) \text{ Use larger of the two results.}$$

$$RR = \frac{\overline{I} \overline{R}}{PLSI}$$

$$TRD = \frac{\overline{I} \overline{I}}{PLSI}$$
